

- 1) The graph on the left has neither Euler path nor Hamiltonian cycle.  
 The graph on the right has an Euler path:  $a-b-c-f-e-c-g-b-d-g-e-d-a$   
 and a Hamiltonian cycle:  $a-b-c-f-e-g-d-a$ .

2)   $A^{(2)} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 \end{pmatrix}$   $A^{(3)} = \begin{pmatrix} 2 & 2 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix} = D$

3) i) Let  $A$  be the adjacency matrix of  $G$ ,  $A = \{a_{ij}\}$ . Then  $A^2[i,j] = \sum_{k=1}^n a_{ik}a_{kj}$ . If  $a_{ik} = p$  and  $a_{kj} = q$  then there are  $(pq)$  paths of length 2 from  $i$  to  $j$  going through  $k$ . Adding the mutually exclusive possibilities for the paths of length 2 to use any node on the graph as an intermediary point, we have  $A^2[i,j] = \sum_{k=1}^n a_{ik}a_{kj}$  paths of length 2 from node  $i$  to node  $j$ .

ii) By induction. The base case was settled in i). Assume  $A^k[i,j]$  counts the number of paths of length  $k$  from  $i$  to  $j$ . Then

$$A^{k+1}[i,j] = \sum_{l=1}^n A^k[i,l]a_{lj}$$

clearly counts the possibilities for paths of length  $k+1$  from  $i$  to  $j$  similarly to the argument from part i) in the proof.

- 4) A connected directed graph will have an Euler path iff either:
- All nodes have out-degree equal to their in-degree.
  - One node has an in-degree greater by 1 than its out-degree and another node has an out-degree greater by 1 than its in-degree, while all other nodes have equal in- and out-degrees.

5) This graph has no leafs and no nodes with more than two edges adjacent to them; it is a polygon. A polygon has a Hamiltonian cycle; start at any node.

6) i) Level 1:  $a$ ; Level 2:  $b, d$ ; Level 3:  $c, g, e$ ; Level 4:  $f$

ii)  $a-b-c-e-d-(e)-f-(e)-g$

7) i)

The shortest path is 1-2-3-8 of length 11.

8) a) Euler paths exist

- for  $m = n = 1$
- for  $m = 2$  and  $n \in \mathbb{N}_{\text{odd}}$  or vice versa
- for  $m, n \in \mathbb{N}_{\text{even}}$

b) Hamiltonian circuits exist for  $m = n \geq 2$ .

9) By contradiction. Suppose that  $T$  is a minimal spanning tree that does not include the arc  $a$ . Arc  $a$  is then part of a cycle. Remove a different higher weight arc from this cycle. This results in a spanning tree with lower weight.

10) As the depth-first search algorithm is moving through the graph if the current node has on its adjacency list a visited node other than the parent node the graph has a cycle.

The already visited node  $a$  is on the adjacency list of node  $d$ .
